What happens if a lithium-ion battery is connected parallel?

Uneven electrical current distribution in a parallel-connected lithium-ion battery pack can result in different degradation rates and overcurrent issues in the cells. Understanding the electrical current dynamics can enhance configuration design and battery management of parallel connections.

How to manage cell imbalances in a battery pack?

Cell balancing is often considered as the first option to manage cell imbalances in a battery pack. However, cell balancing in parallel connections requires cells to be connected through DC-DC or DC-AC converters, as shown in Fig. 13. The current of each cell can then be individually controlled.

How does a parallel battery pack work?

In other words, for a parallel battery pack, the initial input total current is the current of a cell multiplied by the number of branches. At the same time, as the charging process goes on, the overpotential will decrease, requiring subsequent control.

Why is matched internal resistance important in a battery pack?

This phenomenon suggests that matching internal resistance is critical in ensuring long cycle life of the battery pack. Bruen et al. investigated the current distribution and cell temperature within parallel connections.

Why do lithium ion batteries need to be connected in series?

To meet the power and energy requirements of the specific applications, lithium-ion battery cells often need to be connected in series to boost voltage and in parallel to add capacity. However, as cell performance varies from one to another [2,3], imbalances occur in both series and parallel connections.

How does temperature affect the electrochemical re-action of parallel battery pack?

At the start of charging, a total current is input to the parallel battery pack model. Because the diffusion process has not been established at the start of charging, temperature only affects the electrochemical re-action. The temperature is lower, and the risk of Li plating is more.

The performance of lithium-ion battery modules is highly dependent not only on the thermal management system, but also on the connection design in module formation. Herein, we analyze the cell-to-cell inconsistency and evaluate the comprehensive performance of the air-cooled battery modules with different parallel connection topologies.

Compared to the individual cell, fast charging of battery packs presents far more complexity due to the cell-to-cell variations [11], interconnect parallel or series resistance [12], cell-to-cell imbalance [13], and other factors. Moreover, the aggregate performance of the battery pack tends to decline compared to that of the cell level [14]. This results in certain cells within ...

Lithium-ion batteries (LIBs) have gained substantial prominence across diverse applications, such as electric vehicles and energy storage systems, in recent years [[1], [2], [3]].The configuration of battery packs frequently entails the parallel connection of cells followed by series interconnections, serving to meet power and energy requisites [4].

20.2.1 Introduction. To date, on-road vehicles have had battery packs built with lead-acid, nickel-metal hydride, sodium-nickel chloride, and lithium-ion cells, and likely others. A battery pack must perform a number of tasks. The foundation of battery pack design is formed by the need for high levels of safety consistent with transportation applications.

There are many approaches being used to improve the reliability of lithium-ion battery packs (LIBPs). Among them, fault-tolerant technology based on redundant design is an effective method [4, 5].At the same time, redundant design is accompanied by changes in the structure and layout, which will affect the reliability of battery packs.

individual batteries are subject to certain inconsistencies due to the manufacturing process and operating environment factors (Dai et al., 2021). This inconsistency gradually accumulates, thereby increasing the gap in individual recyclable capacity and reducing the overall performance of the battery packs.

The inconsistency within Li-ion battery packs, also known as cell variation, manifests two main aspects. 1) Cells have inherent inconsistency because of minor errors and deviations in their production processes, such as electrode fabrication, assembly, formation, and detection [[3], [4], [5]].
